*Fernando Pereira*  
*Instituto Superior Técnico*

# Multilevel Photographic Image Coding (gray and colour)

## OBJECTIVE

**Efficient representation of multilevel photographic images  
(still pictures) for storage and transmission.**

# Applications

- ★ Digital cameras
- ★ Image databases, e.g. museums, maps
- ★ Desktop publishing
- ★ Colour fax
- ★ Medical images
- ★ ...
- ★ and Digital cinema (!)

# The Image Representation Problem ...

**A image is created and consumed as a set of  $M \times N$  luminance and chrominance samples with a certain number of bits per sample (P).**

**Thus, the total number of bits ( $M \times N \times P$ )  
- and so the memory and bandwidth –  
necessary to PCM digitally represent an  
image is HUGE !!!**

# Image (Source) Coding Objective

**Image coding/compression deals with the efficient representation of images, satisfying the relevant requirements.**

**And these requirements keep changing, e.g., coding efficiency, error resilience, random access, interaction, editing, to address new applications and functionalities ...**

# Where does Compression come from ?

★ **REDUNDANCY** – Regards the similarities, correlation and predictability of samples and symbols corresponding to the image/audio/video data.

-> redundancy reduction does not involve any information loss, implying it is a reversible process -> *lossless coding*

★ **IRRELEVANCY** – Regards the part of the information which is imperceptible for the visual or auditory human systems.

-> irrelevancy reduction involves removing non-redundant information, implying it is an irreversible process -> *lossy coding*

**Source coding exploits these two concepts: for this, it is necessary to know the source statistics and the human visual/auditory systems characteristics.**

# Image Coding: Multiple Solutions

★ DCT-based transform coding, e.g. JPEG standard

JPEG

★ Fractal-based coding

★ Vector quantization coding

★ Wavelet-based coding, e.g. JPEG 2000 standard

JPEG  
2000

★ Lapped biorthogonal-based transform coding, e.g. JPEG XR standard

★ ...

# The JPEG Standard

(Joint Photographic Experts Group, joint ISO & ITU-T)

# Objective

**Definition of a generic compression standard for multilevel photographic images considering the requirements of most applications.**

# Interoperability, thus Standards !

★ **Image coding is used in the context of many applications where interoperability is an essential requirement.**

★ **The interoperability requirement is satisfied through the specification of a **coding standard** which represents a voluntary agreement between multiple parties.**

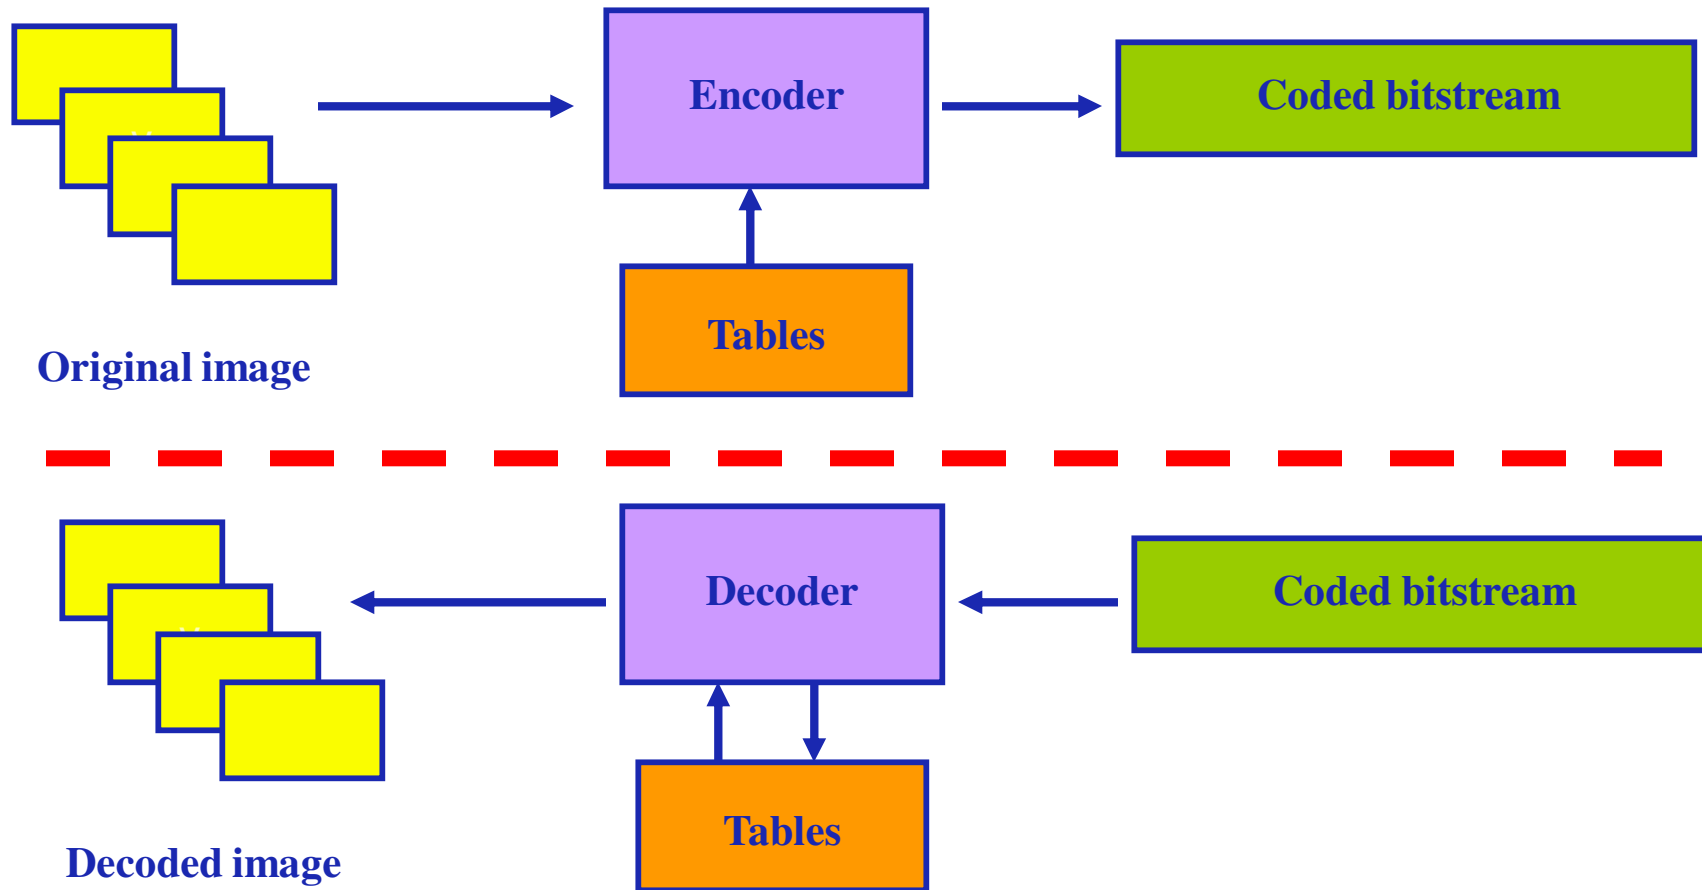

★ **To foster evolution and competition, standards must offer interoperability through the specification of the smallest number of tools.**

# JPEG Standard Major Requirements

≈1985

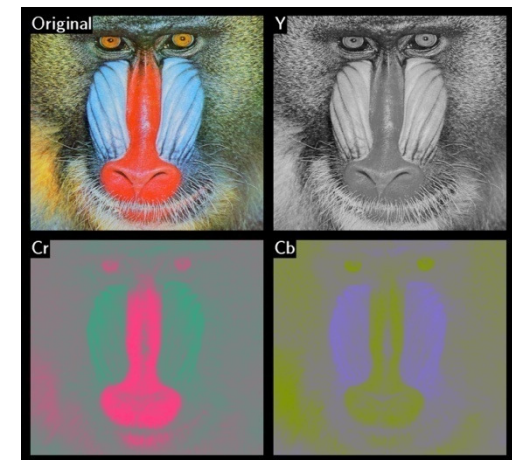

- ★ **Efficiency** - The standard must be based on the most efficient compression techniques, notably for very high quality.
- ★ **Compression/Quality Tunable** - The standard shall allow tuning the quality versus compression efficiency.
- ★ **Generic** - The standard must be applicable to any type of multilevel photographic images without restrictions in resolution, aspect ratio, color space, content, etc.
- ★ **Low Complexity** - The standard must be implementable with a reasonable complexity; notably, its software implementation on a large range of CPUs must be possible.
- ★ **Functional Flexibility** - The standard must provide various relevant operation modes, notably sequential, progressive, lossless and hierarchical.

# JPEG Elements

# What Images can JPEG Encode ?

- ★ Size between  $1 \times 1$  and  $65535 \times 65535$
- ★ 1 to 255 colour components or spectral bands (typically  $Y C_R C_B$  or RGB)
- ★ Each component,  $C_i$ , consists of a matrix with  $x_i$  columns and  $y_i$  lines
- ★ 8 or 12 bits per sample for DCT based compression
- ★ 2 to 16 bits per sample for lossless compression

# Types of JPEG Compression

- ★ **LOSSLESS** - The image is reconstructed with no losses, this means it is mathematically equal to the original; compression factors of about 2-3 may be achieved depending on the image content.
  
- ★ **LOSSY** – The image is reconstructed with losses but with a very high fidelity to the original, if desired (transparent coding); this type of coding allows to achieve higher compression factors, e.g. 10, 20 or more; in the JPEG standard, this type of coding is based on the Discrete Cosine Transform (DCT).

# JPEG Baseline Process

The most used JPEG coding solution is DCT based (lossy), called

**BASELINE SEQUENTIAL PROCESS**

and it is appropriate to inumerous applications. This process is mandatory for all systems claiming JPEG compliance.

# DCT Based Image Coding

# Why do we Transform Blocks ?

**Basically, the transform represents the original signal in another domain where it can be more efficiently coded by exploiting the spatial redundancy.**

- ★ **The full exploitation of the spatial redundancy in the image would require applying the transform to blocks as big as possible, ideally to the full image.**
- ★ **However, the computational effort associated to the transform grows quickly with the size of the block used ... and the added spatial redundancy decreases ...**

**Applying the transform to blocks, typically of  $8 \times 8$  samples, was a good trade-off between the exploitation of the spatial redundancy and the associated computational effort.**

# JPEG Block Coding Sequence

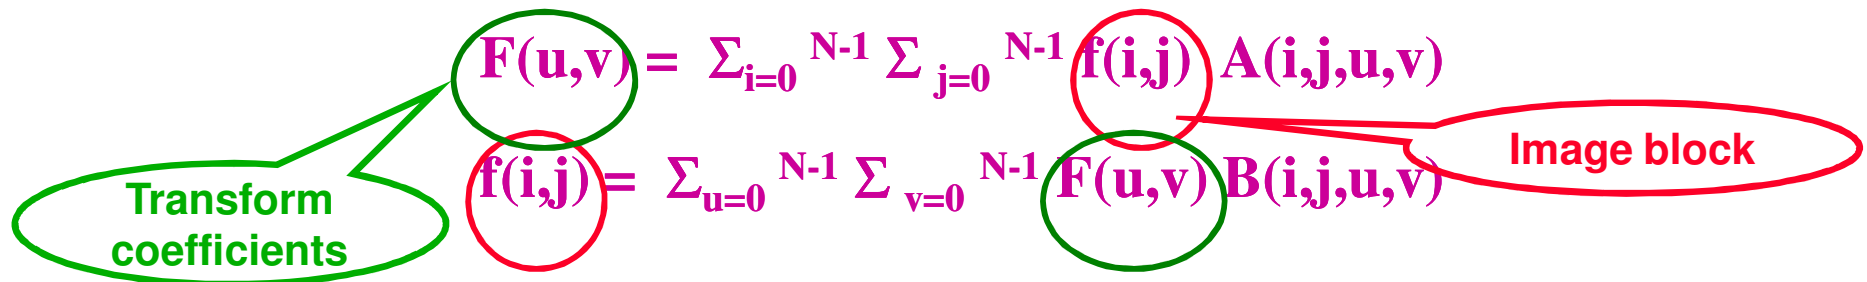

# The Block Effect ...

# Transform Coding

Transform coding involves the division of the image into blocks of  $N \times N$  samples to which the transform is applied, producing blocks with  $N \times N$  transform coefficients.

A transform is formally defined by its direct and inverse transform equations:

$$\begin{aligned}
 F(u,v) &= \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} f(i,j) A(i,j,u,v) \\
 f(i,j) &= \sum_{u=0}^{N-1} \sum_{v=0}^{N-1} F(u,v) B(i,j,u,v)
 \end{aligned}$$

where

$f(i,j)$  – input signal (signal in space)

$A(i,j,u,v)$  – direct transform basis functions

$F(u,v)$  – transform coefficients (signal in frequency)

$B(i,j,u,v)$  – inverse transform basis functions

# Relevant Transform Characteristics

**Unitary transforms are used since they have the following relevant characteristics:**

- ★ Reversibility**
- ★ Orthogonality of the transform basis functions**
- ★ Energy conservation which means the energy in the transform domain is the same as in the spatial domain**

*Note 1: For unitary transforms,  $A^*A=AA^*=I_n$  where  $I_n$  is the identity matrix and  $*$  represents the transpose conjugate operation.*

*Note 2: The transpose matrix results by permuting the lines and columns and vice-versa which means that the transpose is a  $m \times n$  matrix if the original is a  $n \times m$  matrix.*

*Note 3: The conjugate matrix is obtained by substituting each element by its conjugate complex (imaginary part with changed sign).*

# What Shall the Transform Provide ?

- ★ **REVERSIBILITY** – The transform must be reversible since the image to transform has to be recovered again in the spatial domain.
- ★ **INCORRELATION** – The ideal transform shall provide coefficients which are uncorrelated this means each one carries additional/novel information.
- ★ **ENERGY COMPACTATION** – The major part of the signal energy shall be compacted in a small number of coefficients.
- ★ **IMAGE INDEPENDENT TRANSFORM BASIS FUNCTIONS** – Since images show significant statistical variations, the optimal transform should be image dependent; however, the use of image dependent transforms would require its computation as well as its storage and transmission; thus, an image independent transform is desirable even if at some cost in coding efficiency.
- ★ **LOW COMPLEXITY IMPLEMENTATIONS** – Due to the high number of operations involved, the transform shall allow low complexity/fast implementations.

# How to Interpret a Transform ?

The formula for the inverse transform

$$f(i,j) = \sum_{u=0}^{N-1} \sum_{v=0}^{N-1} F(u,v) \cdot B(i,j,u,v)$$

Image  
block

Weights

Basic image  
blocks

expresses that the transform process may be interpreted as a decomposition of each image block in terms of certain basic functions – the transform basis functions – adequately weighted by the transform coefficients.

*The Spectral Interpretation – As most transforms use basis functions with different frequencies (in a broad sense), the decomposition in basis functions assumes a spectral meaning where each coefficient represents the fraction of energy in the image corresponding to a certain basis function/frequency.*

# Advantages of the Spectral Interpretation

**The spectral interpretation allows to easily introduce in the coding process some relevant characteristics of the human visual system which are essential for efficient (lossy) coding.**

★ **The human visual system is less sensitive to the higher spatial frequencies**

**->> coarser coding (through quantization) of the corresponding transform coefficients**

★ **The human visual system is less sensitive to very low or very high luminances**

**->> coarser coding (through quantization) of the DC coefficient for these conditions**

# DCT Based Image Coding

# Transform Coding

Transform coding involves the division of the image into blocks of  $N \times N$  samples to which the transform is applied, producing blocks with  $N \times N$  transform coefficients.

A transform is formally defined by its direct and inverse transform equations:

$$\begin{aligned}
 F(u,v) &= \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} f(i,j) A(i,j,u,v) \\
 f(i,j) &= \sum_{u=0}^{N-1} \sum_{v=0}^{N-1} F(u,v) B(i,j,u,v)
 \end{aligned}$$

where

$f(i,j)$  – input signal (signal in space)

$A(i,j,u,v)$  – direct transform basis functions

$F(u,v)$  – transform coefficients (signal in frequency)

$B(i,j,u,v)$  – inverse transform basis functions

# What Shall the Transform Provide ?

- ★ **REVERSIBILITY** – The transform must be reversible since the image to transform has to be recovered again in the spatial domain.
- ★ **INCORRELATION** – The ideal transform shall provide coefficients which are uncorrelated this means each one carries additional/novel information.
- ★ **ENERGY COMPACTATION** – The major part of the signal energy shall be compacted in a small number of coefficients.
- ★ **IMAGE INDEPENDENT TRANSFORM BASIS FUNCTIONS** – Since images show significant statistical variations, the optimal transform should be image dependent; however, the use of image dependent transforms would require its computation as well as its storage and transmission; thus, an image independent transform is desirable even if at some cost in coding efficiency.
- ★ **LOW COMPLEXITY IMPLEMENTATIONS** – Due to the high number of operations involved, the transform shall allow low complexity/fast implementations.

# Karhunen-Loève Transform (KLT)

The Karhunen-Loève Transform is typically considered the ideal transform because it achieves the

## MAXIMUM ENERGY COMPACTATION

this means, if a certain limited number of coefficients is coded, the KLT coefficients are always those containing the highest percentage of the total signal energy.

The KLT base functions are based on the *eigen vectors of the covariance matrix for the image blocks* (and thus depend on the image block being transformed).

# Why is KLT Never Used ?

**In practice, the use of KLT for image compression is negligible because:**

- ★ **KLT basis functions are image dependent requiring the computation of the image covariance matrix as well as its storage or transmission.**
- ★ **Fast algorithms for its computation are not as good as for other transforms.**
- ★ **There are other transforms without the drawbacks above but still with a energy compactation performance only slightly lower than KLT.**

# Discrete Cosine Transform (DCT)

The DCT is one of the several sinusoidal transforms available; its basis functions correspond to discretized sinusoidal functions.

Transform coefficients

Image block

$$F(u, v) = \frac{2}{N} C(u)C(v) \sum_{j=0}^{N-1} \sum_{k=0}^{N-1} f(j, k) \cos\left(\pi \frac{u(2j+1)}{2N}\right) \cos\left(\pi \frac{v(2k+1)}{2N}\right)$$

$$f(j, k) = \frac{2}{N} \sum_{u=0}^{N-1} \sum_{v=0}^{N-1} C(u)C(v) F(u, v) \cos\left(\frac{u(2j+1)}{2N} \pi\right) \cos\left(\frac{v(2k+1)}{2N} \pi\right)$$

Image block

Transform coefficients

The DCT is the most used transform for image and video compression since its performance is close to the KLT performance for highly correlated signals; moreover, there are fast implementation algorithms available.

# DCT Bidimensional Basis Functions (N=8)

**All existing and  
future images  
can be  
represented with  
these 64 (8×8)  
basic images !!!**

# DCT in JPEG

**Since the DCT uses sinusoidal functions, it is impossible to perform computations with full precision. This leads to (slight) differences in the results for different implementations (decoding mismatch).**

- ★ **To accommodate future implementation developments, the JPEG recommendation does not specify any specific DCT or IDCT implementation.**
- ★ **The JPEG recommendation specifies a fidelity/accuracy test regarding a reference implementation in order to limit the differences caused by the freedom in terms of DCT and IDCT implementation.**

*Note: The DCT is applied to the signal samples with  $P$  bits, with values between  $-2^{P-1}$  and  $2^{P-1}-1$  in order the DC coefficient is distributed around zero.*

# DCT Based Image Coding

# Quantization: Making the Codec Lossy ...

Quantization is the process by which irrelevancy or perceptual redundancy is reduced.

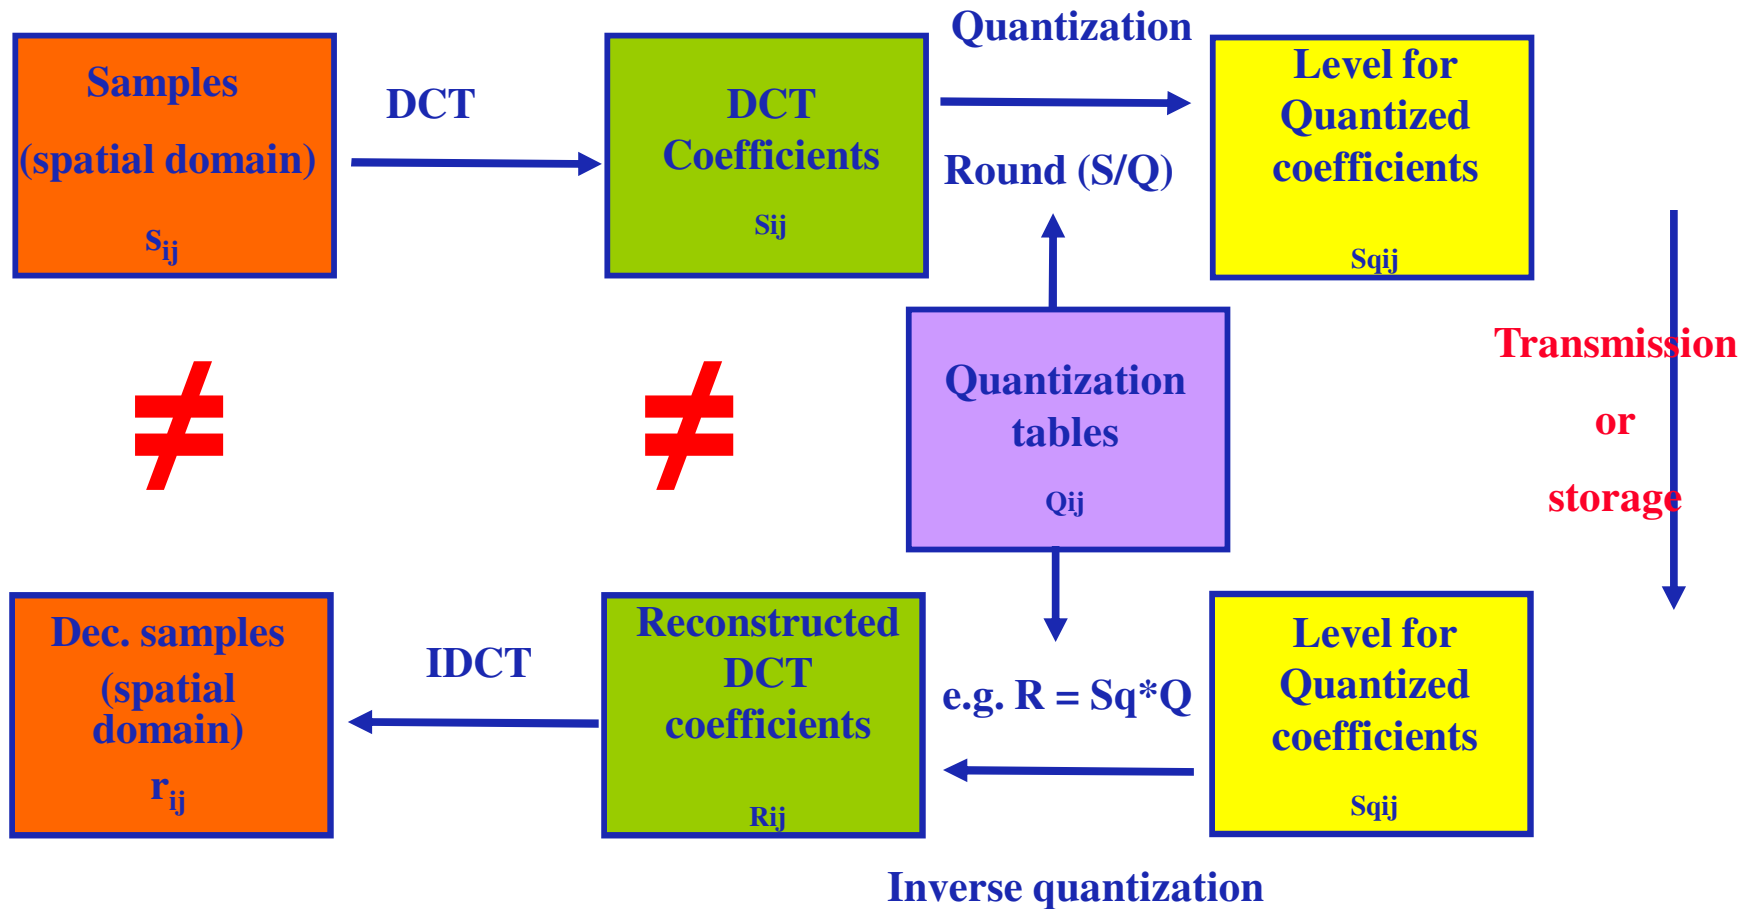

This process is the major responsible for the quality losses (but also the compression factors) in DCT based codecs (but quality may be transparent).

Each quantization step may be selected taking into account the ‘minimum perceptual difference’ for the coefficient in question.

The quantization matrixes are not standardized but there is a suggested solution for ITU-R 601 resolution images (which still has to be coded).

# How Does DCT Coding Work ?

# Quantization Matrices

For transparent quality, JPEG suggests to quantize the DCT coefficients using the values for the ‘minimum perceptual difference’ (for each coefficient) multiplied by 2; for more compression, a multiple of them may be used.

The quantization matrixes have to be always transmitted or at least signalled.

# DCT Based Image Coding

# Zig-Zag Serializing the Quantized Coefficients

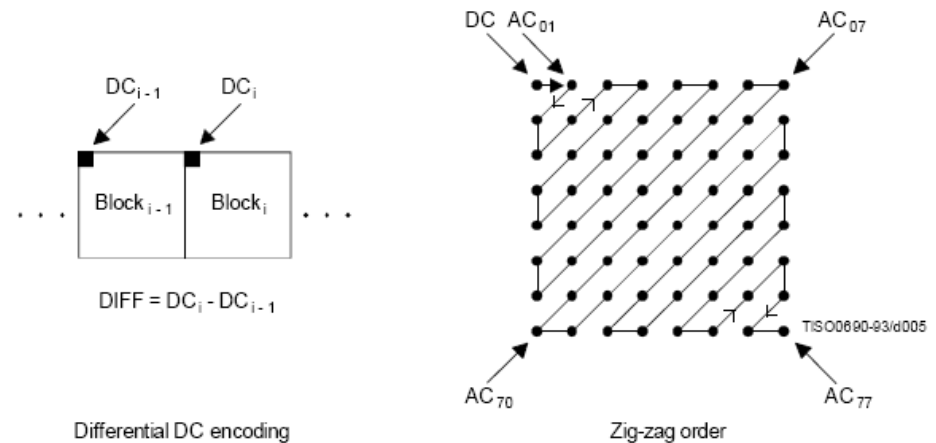

124	25	0	0	0	0	23	0
147	0	13	0	0	78	190	248
126	147	0	0	0	0	0	0
0	10	0	0	15	0	183	119
40	0	0	0	83	0	0	0
94	0	0	173	0	0	0	0
0	0	0	56	0	0	0	0
203	0	0	0	0	0	0	0

Each DCT block is represented as a sequence of (run, level) pairs, e.g. (0,124), (0, 25), (0,147), (0, 126), (3,13), (0, 147), (1,40) ...

- ★ For the decoder to reconstruct the matrix with the quantized DCT coefficients, the position and amplitude of the non-null coefficients has to be coded, one after another.
- ★ The position of each quantized DCT coefficient may be sent in a relative or absolute way.
- ★ The JPEG solution is to send the position of each non-null quantized DCT coefficient through a *run* indicating the number of null DCT coefficients existing between the current and the previous non-null coefficients.

# Generating the Symbols

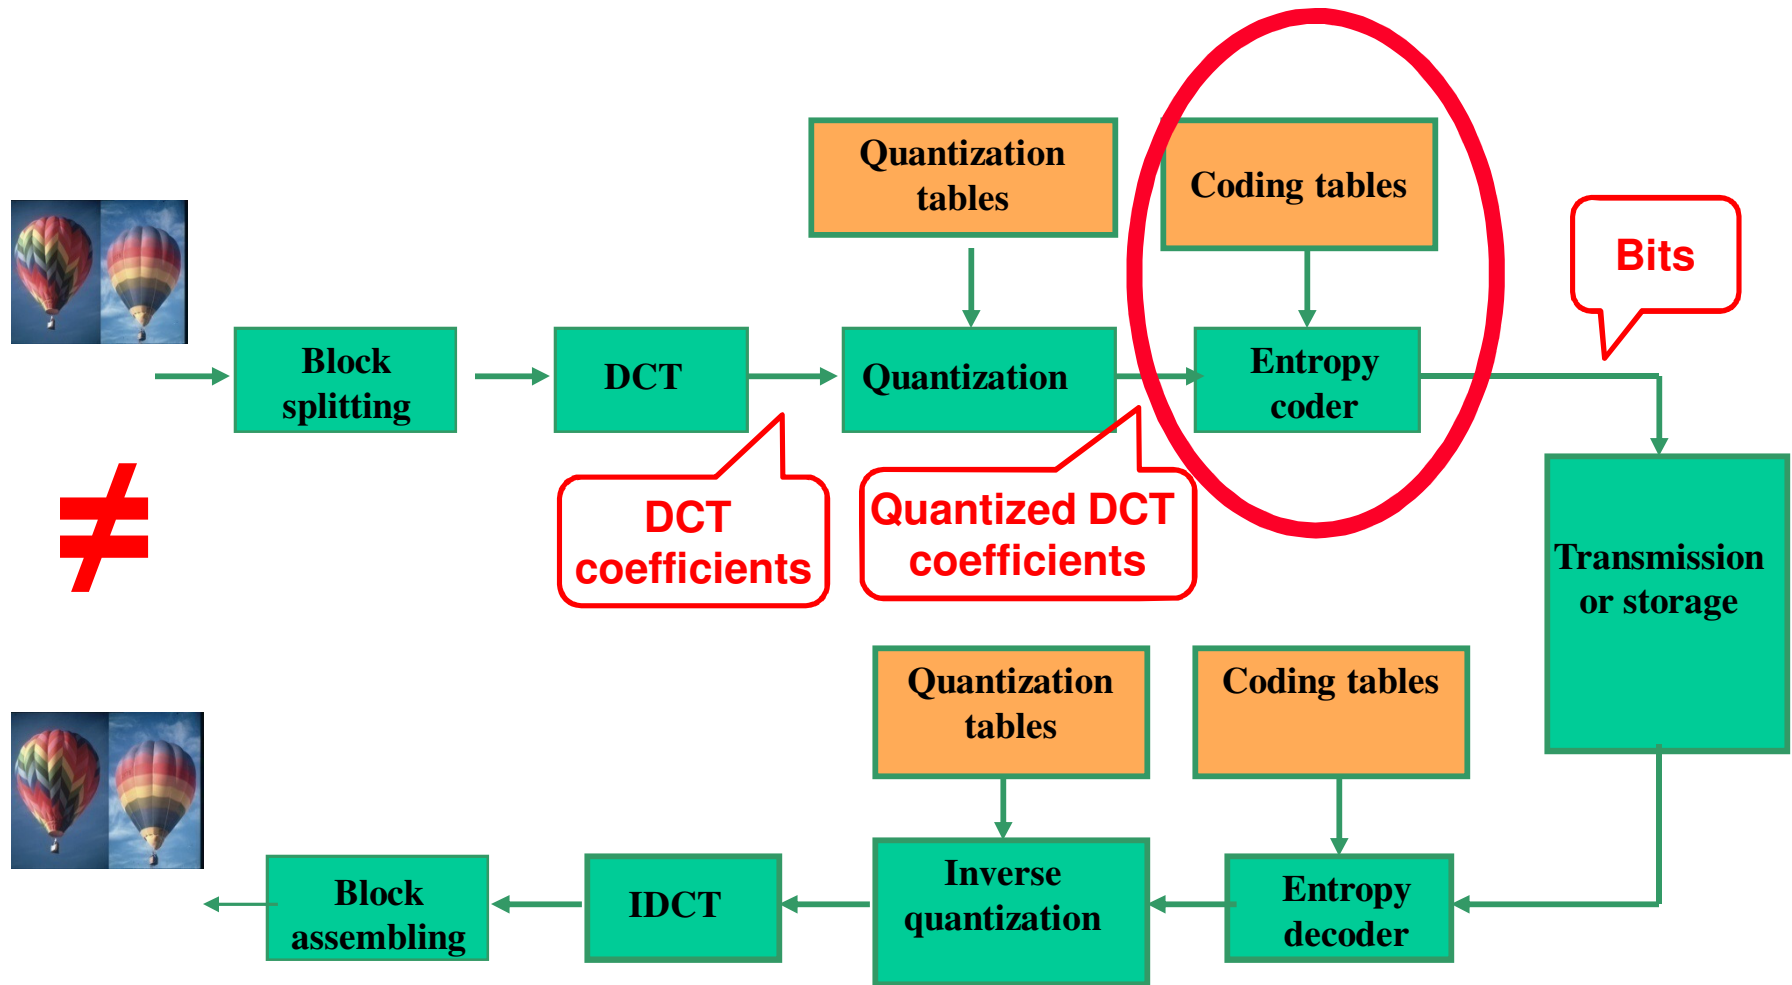

The first step is to decide which symbols, this means which length) pairs represent each 8×8 block; these symbols will be entropy encoded.

- ★ The DC coefficient is treated differently (using differential prediction) because of the high correlation between the DC coefficients of adjacent 8×8 blocks.
- ★ The remaining quantized coefficients are zig-zag ordered to facilitate entropy coding, creating shorter runs; this also means coding the lower frequency coefficients before the higher frequency coefficients in a perceptually prioritized way.

The precise definition of the symbols to encode depends on the DCT operation mode and the type of entropy coding.

# DCT Based Image Coding

# JPEG Coding Model

**JPEG Model:** An image is represented as a sequence of (almost) independent  $8 \times 8$  samples blocks with each block represented by means of a zig-zag sequence of quantized DCT coefficients using (*run, level*) pairs, terminated by a *End of Block*.

# Information Theory: Source Entropy

**Information Theory states that there is a lower limit for the average number of bits per symbol when coding  $m$  symbols from a source of information, each one with probability  $p_i$ . This limit is given by the source entropy:**

$$\mathbf{H = \Sigma p_i \log_2 ( 1/p_i) \quad \text{bit/symbol}}$$

## ⑩ The source entropy:

- **Measures the average amount of information carried by each symbol output by the source**
- **Is a convex function of the probabilities  $p_i$**
- **Takes its maximum value when all symbols are the same probability (all  $p_i$  are the same)**
- **Takes a maximum value of  $\log_2 m$  bit/symbol**

**Information Theory does not indicate how to obtain a code with this coding efficiency but there are methods which allow to obtain codes with an efficiency as close as desired to the entropy efficiency.**

# Entropy Coding

**Entropy coding allows encoding into bits the symbols issued by a source taking into account their statistical distribution.**

**Entropy coding:**

- (+)** Increases the final compression efficiency
- (+)** Does not degrade the coded signal, this means it is lossless
- (-)** Produces a highly time varying bitstream
- (-)** Increases the sensibility to transmission errors
- (\*)** Provides compression in statistical terms, not necessarily symbol by symbol

# Huffman (VLC) Coding

Símbolo	Probabilidade redução 0	Palav. Código redução 0	Probabilidade redução 1	Palav. Código redução 1
A	0.7	0	0.7	0
B	0.2	1 0	0.3	1
C	0.1	1 1		

Huffman coding allows obtaining a code with an average number of bits per symbol as close as desired to the source entropy.

But this requires knowledge on the source statistics, i.e., symbol probabilities.

**Entropy = 1.157 bit/symbol**  
**( $H = \sum p_i \log_2 (1/p_i)$  bit/symbol)**

**Average code length = 1.3 bit/symbol**

**Efficiency = 1.157/1.3 = 89%**

# Huffman Coding: 2<sup>a</sup> Order Extension

Entropy = 1.157 bit/symbol

Average code length for 2<sup>nd</sup> order extension = 2.33 bit/extension symbol

Average code length = 2.33/2 = 1.165 bit/symbol

Efficiency = 1.157/1.165 = 99,3 %

# JPEG Entropy Coding

**Entropy coding uses the statistics of the symbols to code to reach (lossless) additional (entropy) compression.**

**For JPEG Baseline, entropy coding includes two phases:**

- ★ **(RUN, LEVEL) PAIRS TO SYMBOLS** - Conversion of the sequence of (run, level) pairs associated to the DCT coefficients, zig-zag ordered into an intermediary sequence of symbols (symbols 1 and 2 in the following)
- ★ **SYMBOLS TO BITS** - Conversion of the sequence of intermediary symbols into a sequence of bits without externally identifiable boundaries

# Entropy Coding: Intermediary Symbols

Each non-null AC coefficient is represented combining its quantization *level* (*amplitude*) with the number of null DCT coefficients preceding it in the zig-zag scanning (*position*) using a *run* in 0...62.

Each (*run, level*) pair associated to a non-null AC coefficient is represented by a pair of symbols:

- ★ *Run* - number of null DCT coefficients preceding the coefficient being coded in the zig-zag scanning
- ★ *Size* – number of bits used to code the *Level* (this means Symbol 2)
- ★ *Level* – quantized amplitude of the AC coefficient to be coded

Each DC coefficient is represented in the same way, with the *run* equal to zero.

# Entropy Coding: Generating the Bits

**Symbol 1 - Huffman (bidimensional)**    **Symbol 2 - VLI**

- ★ **Symbol 1 for the DC and AC coefficients is coded with the Huffman table corresponding to the component in question.**
- ★ **Symbol 2 is coded with a *Variable Length Integer* (VLI) code which length depends on the level being coded.**
- ★ **VLI codes are VLC codes where the codeword length is previously indicated; they are based on a complement to 2 notation.**
- ★ **VLI codes may be computed instead of stored (important for big codes) and are not significantly less efficient than Huffman codes.**

# Compression versus Quality

**JPEG offers the following levels of compression/quality for sequential DCT based coding, considering colour images with medium complexity:**

- ★ **0.25 - 0.5 bit/pixel – medium to good quality; enough for some applications**
- ★ **0.5 - 0.75 bit/pixel – good to very good quality; enough for many applications**
- ★ **0.75 - 1.5 bit/pixel – excellent quality; enough for most applications**
- ★ **1.5 - 2.0 bit/pixel – transparent quality; enough for the most demanding applications**

**These compression/quality levels are only indicative since the compression always depends on the specific image content, notably if there is more or less spatial redundancy and irrelevancy.**

**The quality level may be controlled through the quantization steps.**

# Performance Assessment Experiment

## Conditions:

- ★ Baseline coding process (DCT based), using the quantization tables suggested in the JPEG standard and Huffman/VLI coding with optimized tables and ITU-T 601 spatial resolution.
- ★ A JPEG with optimized tables is simply a JPEG stream including custom Huffman tables created after the statistical analysis of the image's unique content.

## Conclusions:

- ★ Most of the signal energy is concentrated on the luminance component.
- ★ Most of the bits are used for AC DCT coefficients.
- ★ *Barb1* and *Barb2* test images, which are richer in high frequencies, lead to lower compression factors, although still within the JPEG compression/quality targets.

# Summary: How Does JPEG Compress ?

## ★ Spatial Redundancy

- Image samples statistically dependent are converted into uncorrelated DCT coefficients with the signal energy concentrated in the smallest possible number of coefficients

## ★ Irrelevancy

- DCT coefficients are quantized using psychovisual criteria

## ★ Statistical Redundancy

- The statistics of the symbols is exploited using *run-length* coding and Huffman entropy coding (or arithmetic coding)

# JPEG Extensions

# JPEG Operation Modes

The various JPEG operation modes address the need to provide solutions for a large range of applications with different requirements.

- ★ **SEQUENTIAL MODE** – Each image component is coded in a single scan (from top to bottom and left to right).
- ★ **PROGRESSIVE MODE** - The image is coded with several scans which offer a successively better quality (but same spatial resolution).
- ★ **HIERARCHICAL MODE** - The image is coded in several resolutions exploiting their mutual dependencies, with lower resolution images available without decoding higher resolution images.
- ★ **LOSSLESS MODE** – This mode guarantees the exact reconstruction of each sample in the original image (mathematical equality).

For each operation mode, one or more codecs are specified; these codecs are different in the sample precision (bit/sample) or the entropy coding method.

Decoding 3

# JPEG Progressive Mode

**The image is coded with successive scans. The first scan gives very quickly an idea about the image content; after, the quality of the decoded image is progressively improved with the successive scans (quality layers).**

**The implementation of the progressive mode requires a memory with the size of the image to store the quantized DCT coefficients (11 bits for the baseline process) which will be partially coded with each scan.**

**There are two methods of implementing the progressive mode:**

- ★ SPECTRAL SELECTION – Only a specified 'zone' of DCT coefficients is coded in each scan (typically goes from low to high frequencies)**
- ★ GROWING PRECISION – DCT coefficients are coded with successively higher precision, bitplane after bitplane**

**The spectral selection and successive approximations methods may be applied separately or combined.**

# Progressive Modes: Spectral Selection and Growing Precision

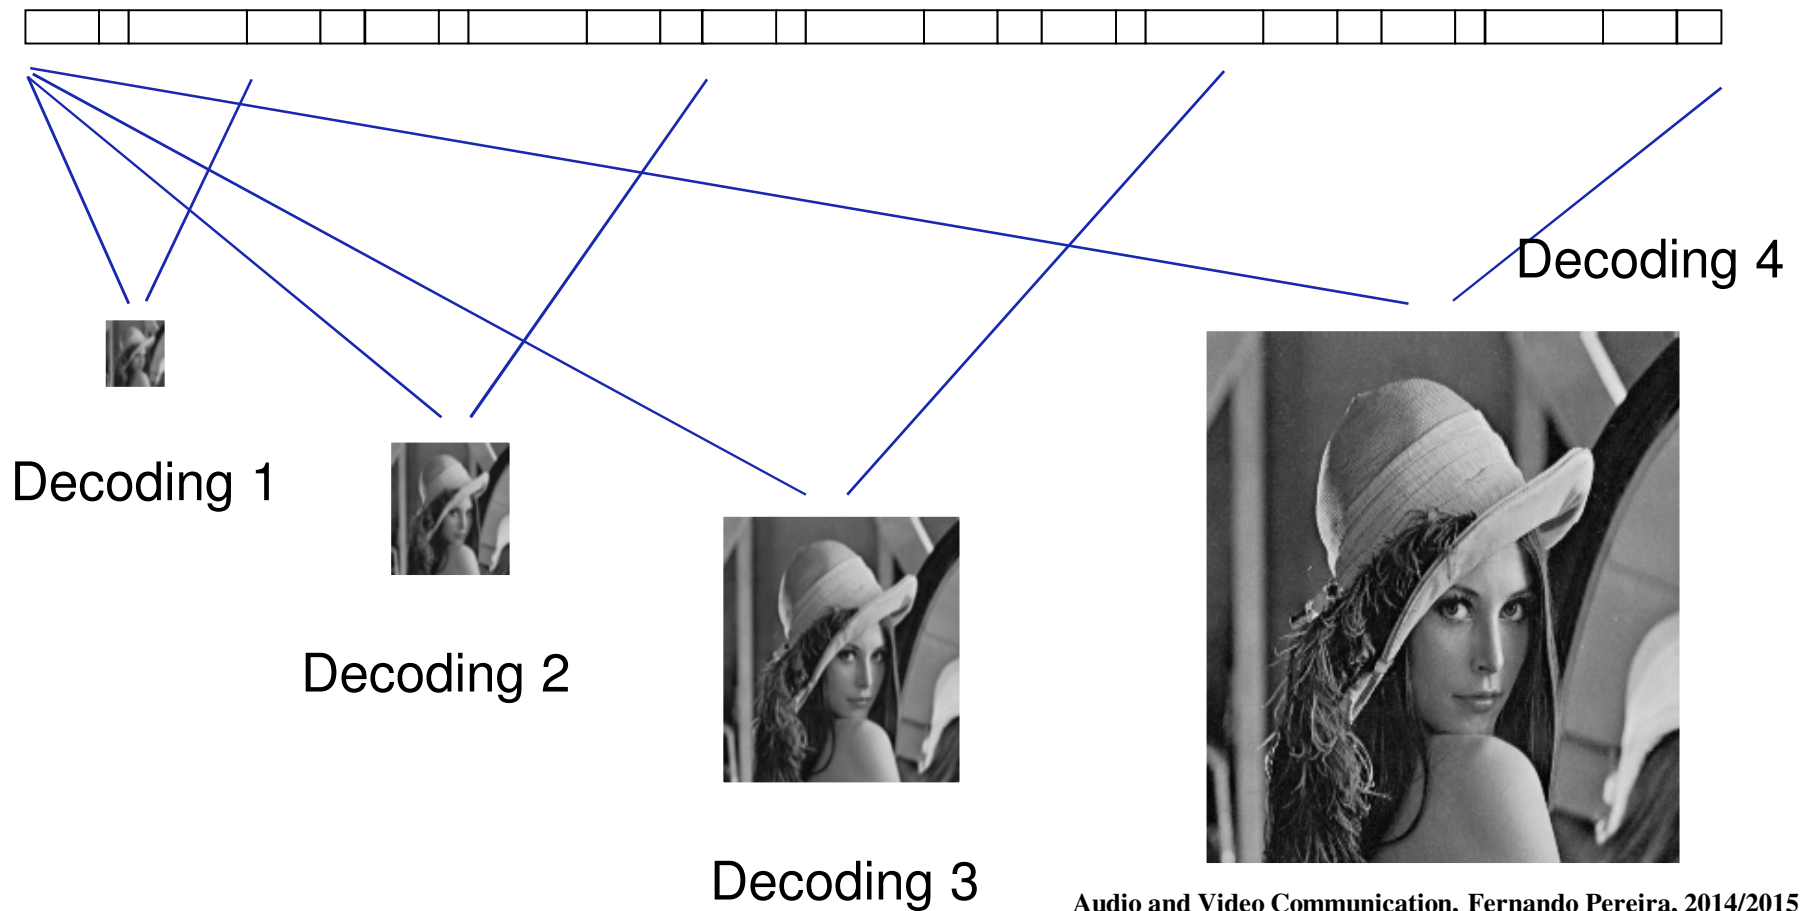

Each layer brings and increasing number of DCT coefficients

Each layer brings an increasing precision for each coefficient

# Hierarchical Mode or Spatial Scalability ...

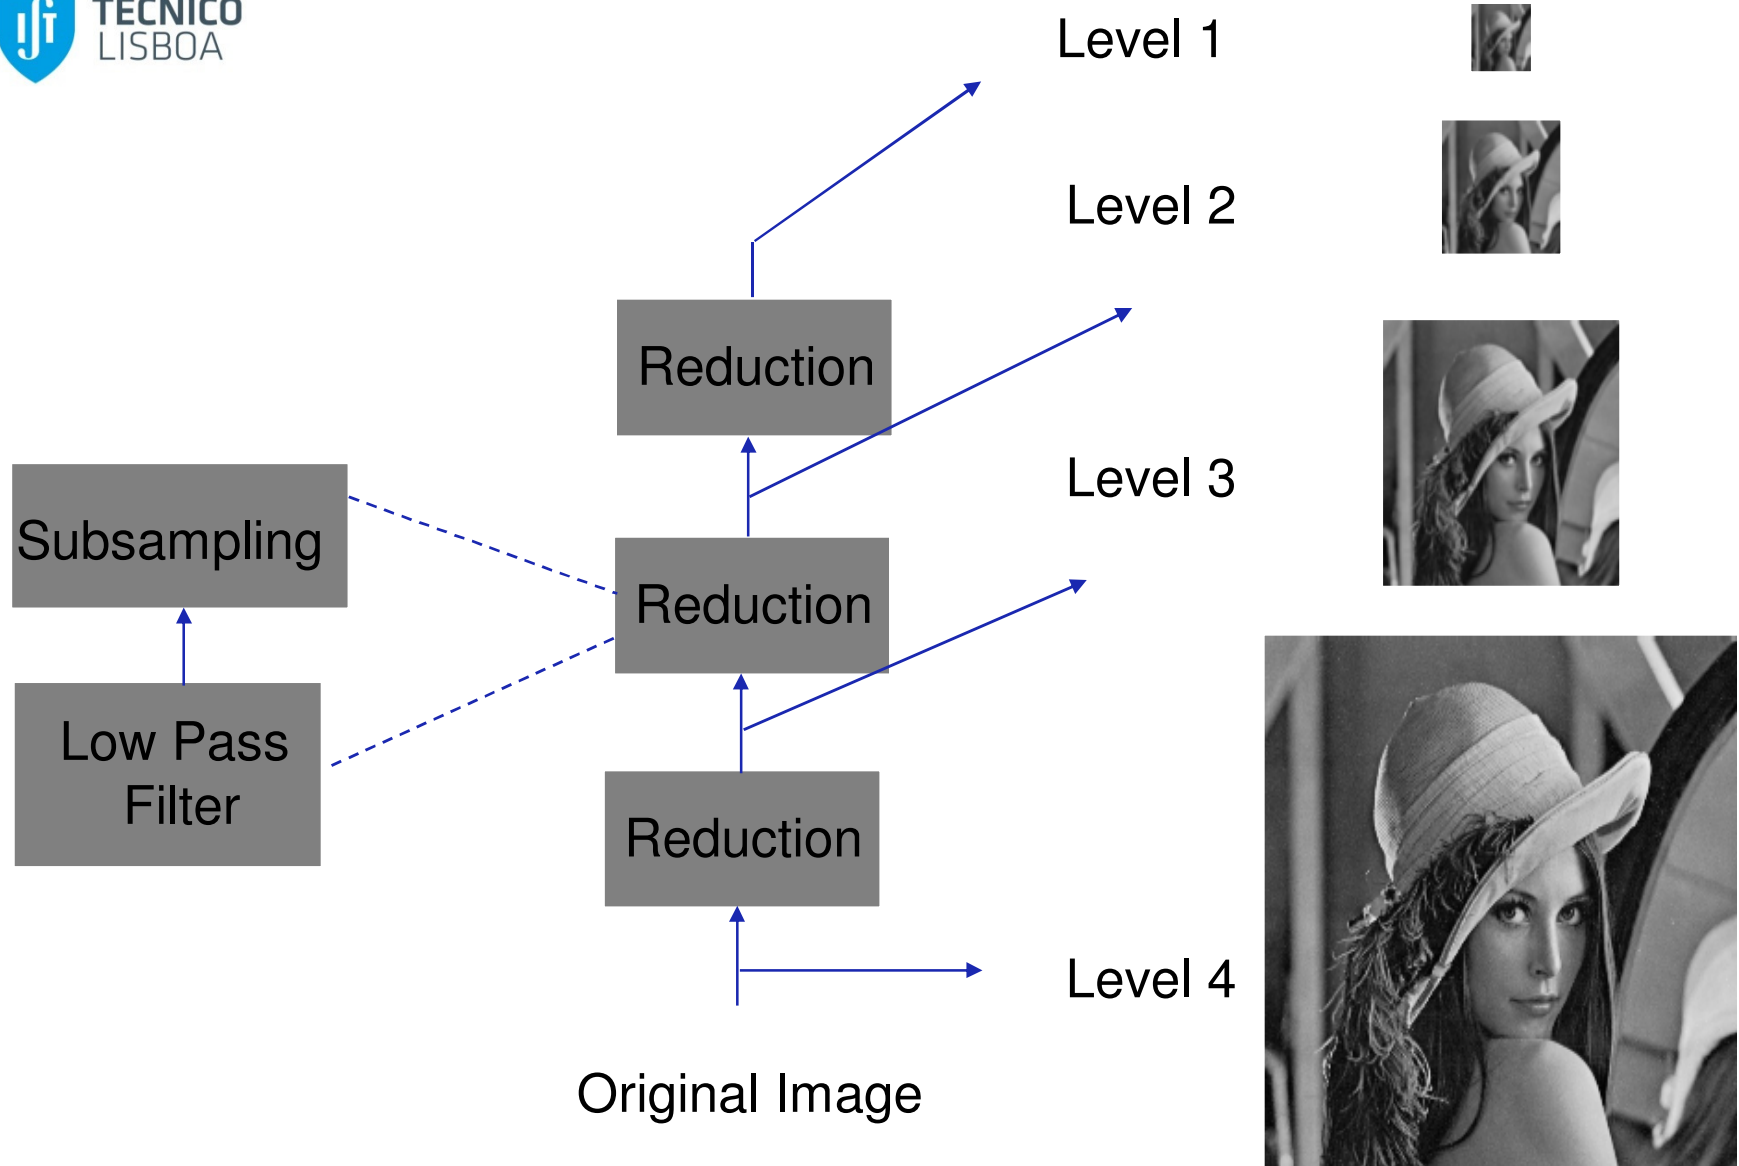

Scalable stream

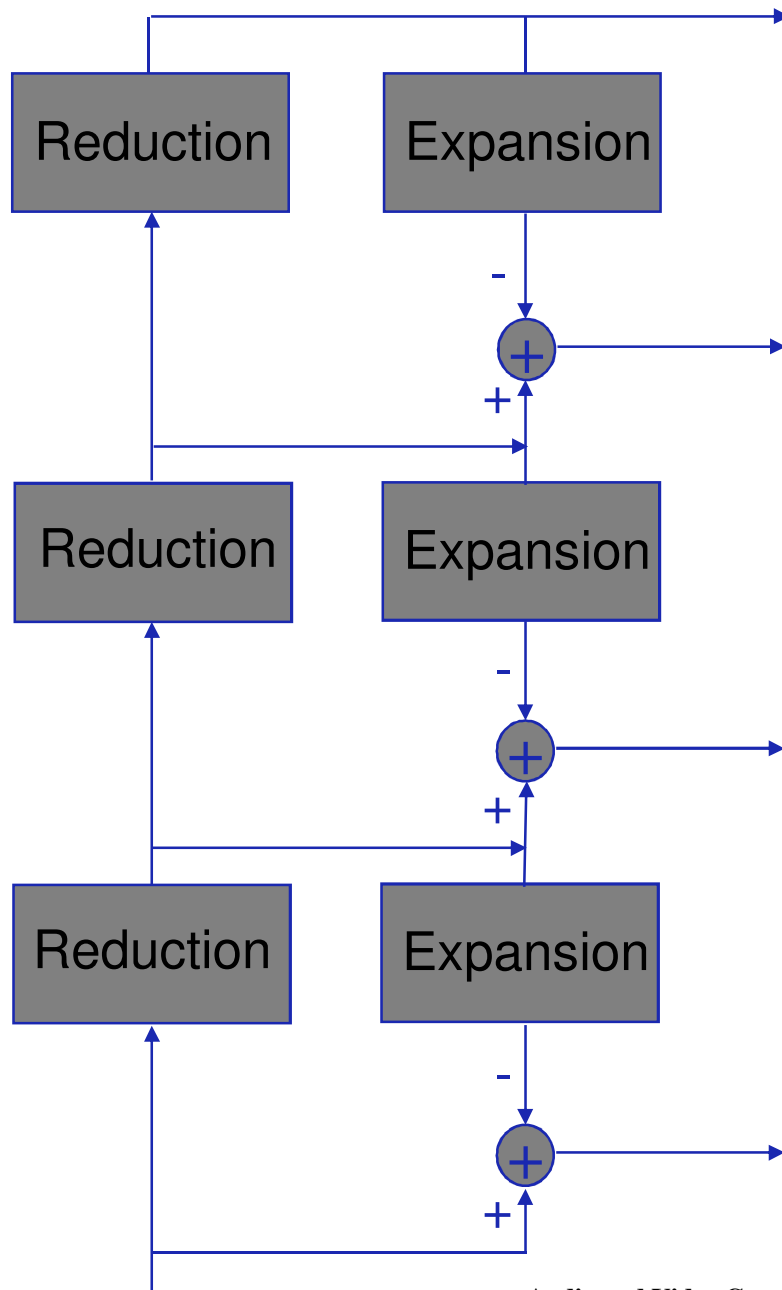

# Hierarchical Mode

- ★ **The hierarchical mode implements a pyramidal coding of the image with several spatial resolutions. Each (higher) resolution multiplies by 2 the number of vertical and horizontal samples.**
- ★ **JPEG hierarchical coding may integrate in the various layers, lossless coding as well as DCT based coding.**

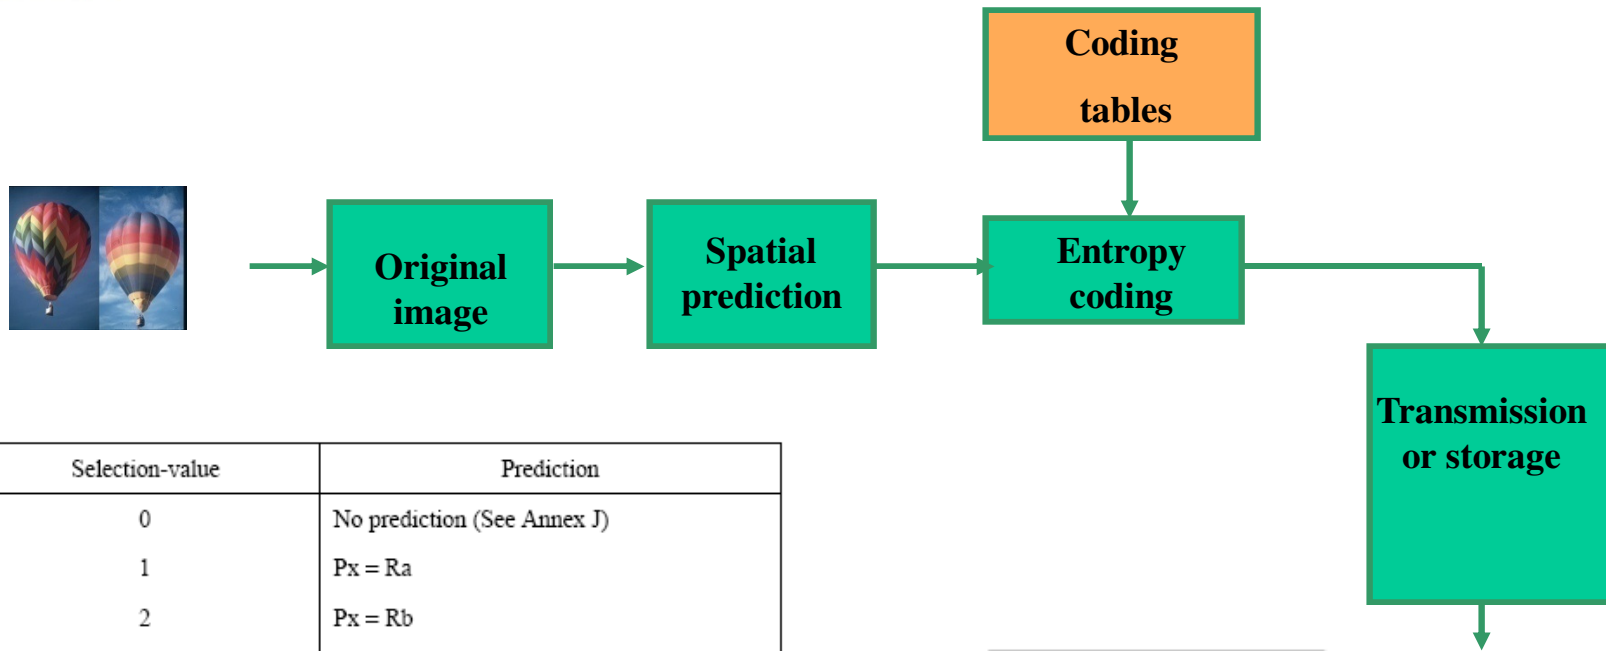

Original Image

# JPEG Lossless Mode

**The JPEG lossless mode is based on a spatial prediction scheme. The prediction combines the values of, at most, 3 adjacent pixels. Finally, the prediction mode and the prediction error are coded.**

- ★ **This JPEG coding mode is rather popular for medical imaging.**
- ★ **The definition of a DCT based lossless mode would require a much more precise/rigid definition of the codecs, e.g. DCT implementation.**
- ★ **Two JPEG lossless codecs are specified, one using Huffman coding and another using arithmetic coding.**
- ★ **The codecs may use any precision between 2 and 16 bit/sample.**
- ★ **The JPEG lossless mode offers ≈ 2:1 compression for colour images of medium complexity.**
- ★ **There is also a JPEG-LS standard developed later, allowing to achieve better compression factors (≈ 3:1).**

# Lossless Coding

Selection-value	Prediction
0	No prediction (See Annex J)
1	$P_x = R_a$
2	$P_x = R_b$
3	$P_x = R_c$
4	$P_x = R_a + R_b - R_c$
5	$P_x = R_a + ((R_b - R_c)/2)^{a)}$
6	$P_x = R_b + ((R_a - R_c)/2)^{a)}$
7	$P_x = (R_a + R_b)/2$

a) Shift right arithmetic operation

**$P_x$  is the prediction and  $R_a$ ,  $R_b$ , and  $R_c$  are the reconstructed samples immediately to the left, above, and diagonally to the left of the current sample.**

**$x$  is the sample to code**
