# Coding Changing Faces ...

# Recommendation H.261: Objectives

~1985

Efficient coding of videotelephony and videoconference visual data with a minimum acceptable quality using a bitrate from 40 kbit/s to 2 Mbit/s, targeting synchronous channels (ISDN) at  $p \times 64$  kbit/s, with  $p=1, \dots, 30$ .

**This is the first international video coding standard with relevant market adoption, thus introducing the notion of backward compatibility in video coding standards.**

# H.261: Image Format

Two spatial resolutions are possible:

- **CIF (Common Intermediate Format)** -  $288 \times 352$  samples for luminance (Y) and  $144 \times 176$  samples for each chrominance (U,V) this means a 4:2:0 subsampling format, with ‘quincux’ positioning, progressive, 30 frame/s with a 4/3 aspect ratio.
- **QCIF (Quarter CIF)** – Similar to CIF with half spatial resolution in both directions this means  $144 \times 176$  samples for luminance and  $72 \times 88$  samples for each chrominance.

**All H.261 codecs must work with QCIF and some may be able to work also with CIF (spatial resolution is set after initial negotiation).**

T1500340-86

# Images, Groups Of Blocks (GOBs), Macroblocks and Blocks

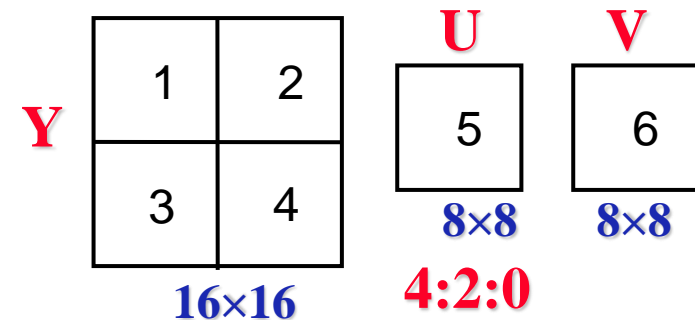

QCIF

CIF

The video sequence is spatially organized according to a hierarchical structure with 4 levels:

- Images/Frames
- Group of Blocks (GOB)
- Macroblocks (MB) – 16×16 pixels
- Blocks - 8×8 samples

LOSSLESS →

- **Temporal Redundancy**

Predictive coding: temporal prediction residues  
without and with motion compensation

- **Spatial Redundancy**

Transform coding (Discrete Cosine Transform, DCT)

- **Statistical Redundancy**

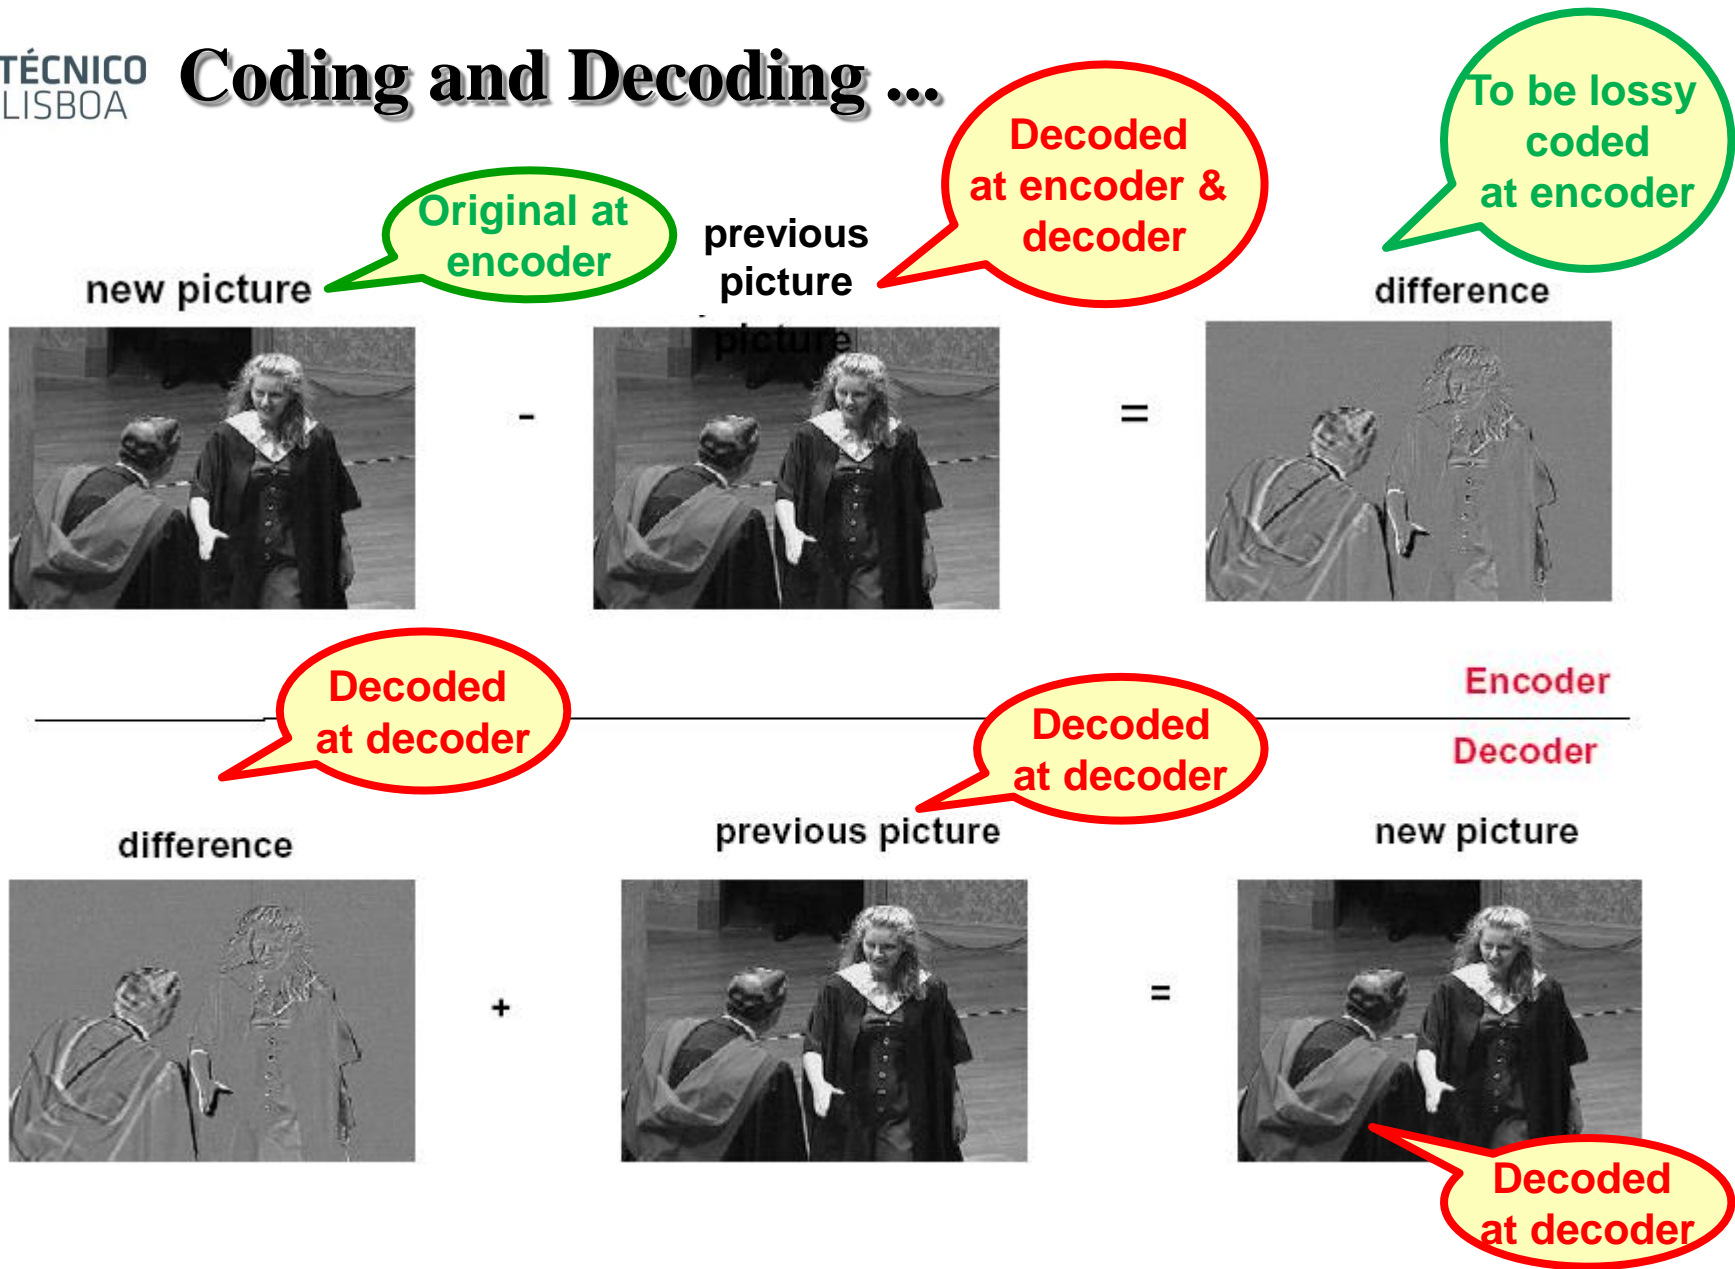

Huffman entropy coding

- **Irrelevancy**

Quantization of DCT coefficients

# Coding and Decoding ...

# Motion in Action ... Not New, Just Displaced !

The key idea is to exploit as much as possible what the decoder already knows !

# Motion Estimation by Macroblock Matching

Decoded Frame  $i-1$

(available at encoder and decoder)

Original Frame  $i$

(ONLY available at encoder)

The best MB prediction from the previous decoded frame is the one minimizing an error metric, e.g. MSE or MAE, between the original MB in frame  $i$  and the candidate (displaced) MBs in frame  $i-1$ .

$$MSE = \frac{1}{n} \sum \underbrace{\left( y - \hat{y} \right)^2}_{\substack{\text{The square of the difference} \\ \text{between actual and} \\ \text{predicted}}}$$

# Motion Search: Where Worthwhile while Reducing Complexity ?

Searching area

Previous decoded image  
available at the decoder  
AND encoder

In H.261, this motion  
vector search area has  
a size of  $\pm 15$  pixels in  
both directions.

Original image to encode  
ONLY available at encoder

# Motion Vectors at Different Spatial Resolutions

**Low resolution**

**Higher resolution**

# Motion is More than Translations !

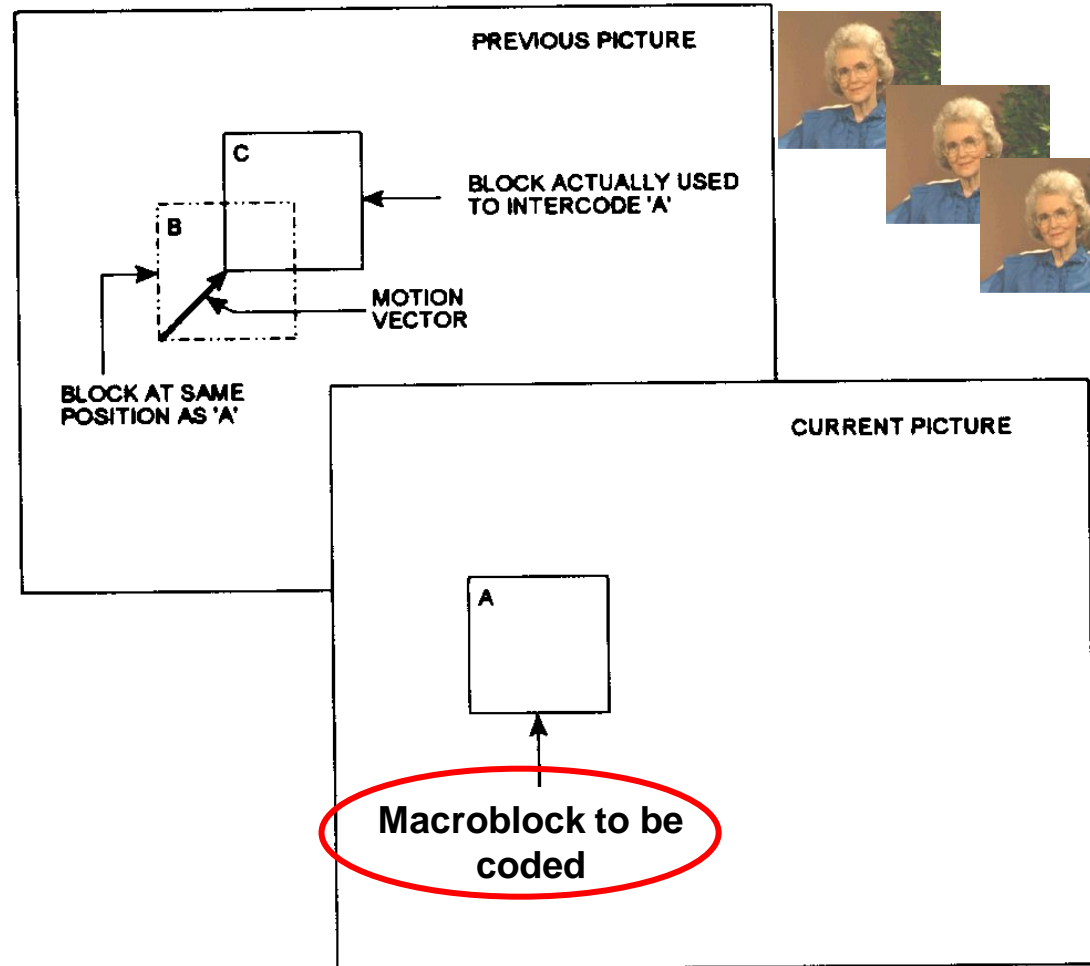

**Clearly, a (translational) motion vector cannot represent well many types of motion ... But it is still very much worthwhile !**

# Predicting in Time ... With or Without Motion

Two main temporal prediction coding modes (**Inter modes**) are available for each MB:

- **Inter with No motion vector:**  
Prediction from the same position in the previous frame
- **Inter With a motion vector:**  
Prediction from a displaced position in the previous frame

The encoder has to choose the **best coding deal** using some (non-normative) criteria !

# Inter Versus Intra Coding

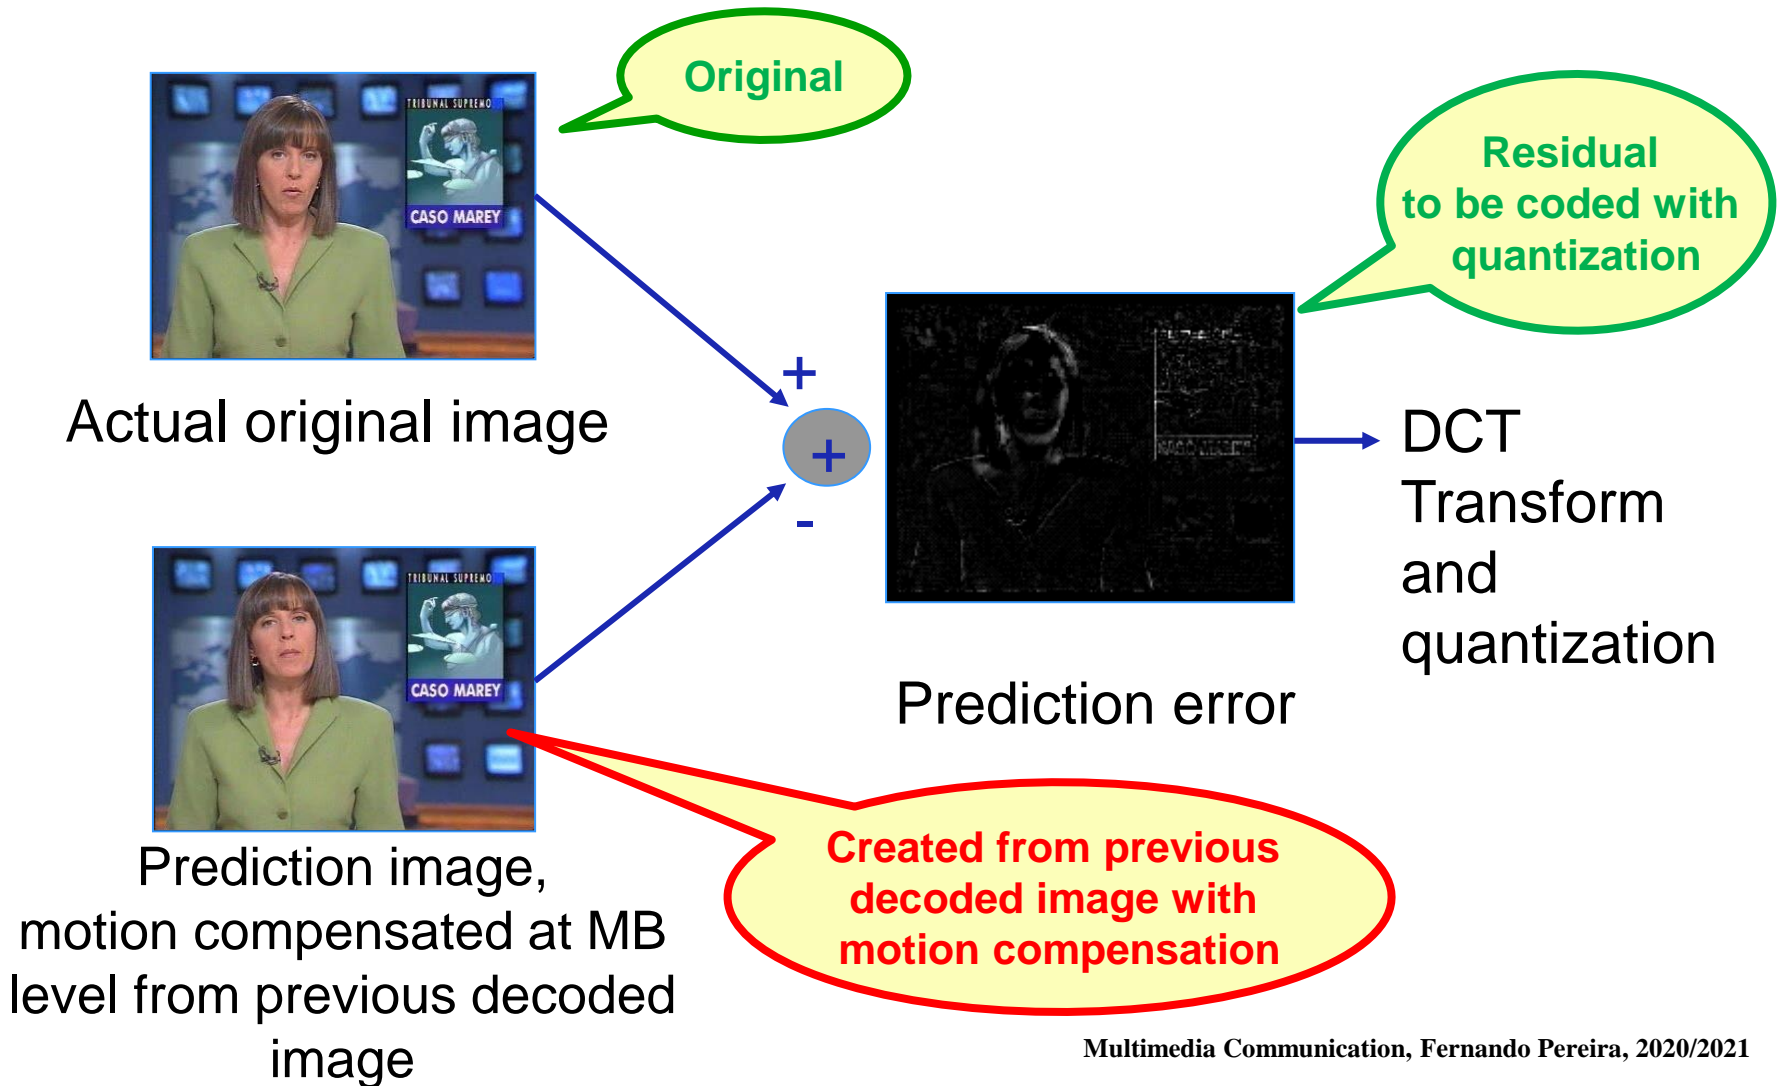

In H.261, the MBs are coded either in Inter or Intra coding mode:

- **INTER CODING MODE** – To be used when there is substantial temporal redundancy; may imply the usage or not of motion compensation, i.e. *Inter+MC* and *Inter(+noMC)*.
- **INTRA CODING MODE** – To be used when there is NO substantial temporal redundancy; no temporal predictive coding is used in this case ('absolute' coding like in JPEG is used to exploit the spatial redundancy).

# After Temporal Redundancy, Spatial Redundancy

# Bidimensional DCT Basis Functions (N=8)

Exploiting Spatial  
Redundancy ...

in the usual way ...

now also for the MB  
prediction error ...

$$F(u,v) = \frac{2}{N} C(u)C(v) \sum_{x=0}^{N-1} \sum_{y=0}^{N-1} f(x,y) \cos \frac{(2x+1)u\pi}{2N} \cos \frac{(2y+1)v\pi}{2N}$$

$$f(x,y) = \frac{2}{N} \sum_{u=0}^{N-1} \sum_{v=0}^{N-1} C(u)C(v) F(u,v) \cos \frac{(2x+1)u\pi}{2N} \cos \frac{(2y+1)v\pi}{2N}$$

# H.261 Quantization

Example quantization  
function

- H.261 uses as quantization steps all even values between 2 and 62 (31 quantizers available).
- Within each MB, all DCT coefficients are quantized with the same quantization step with the exception of the DC coefficient for Intra MBs which are always quantized with step 8.
- The usage of a same constant quantization step for all the AC DCT coefficients is motivated by the fact that a prediction error (and not absolute sample values) is being coded.
- H.261 normatively defines the reconstruction values for the quantized coefficients but not the decision values which may be selected to implement different quantization characteristics (uniform or not).

# Serializing the Residual DCT Coefficients

 (1, -1), (0, 3), (0, -1),  
 (0, -1),  
 (10, 5)  
 (X, -7)  
**EOB**

- The transmission of the quantized DCT coefficients requires to send the decoder two types of information about the coefficients: their position and quantization level (for the selected quantization step).
- For each DCT coefficient to transmit, its position and quantization level are represented using a bidimensional symbol

*(run, level)*

where the *run* indicates the number of null coefficients before the coefficient under coding, and the *level* indicates the quantized level of the coefficient.

Small runs and small absolute levels are more probable and entropy coding will exploit that.

# Channel and Coding Bitrates ...

# Encoder: the Winning Tools Cocktail !

# Decoder: the Slave !

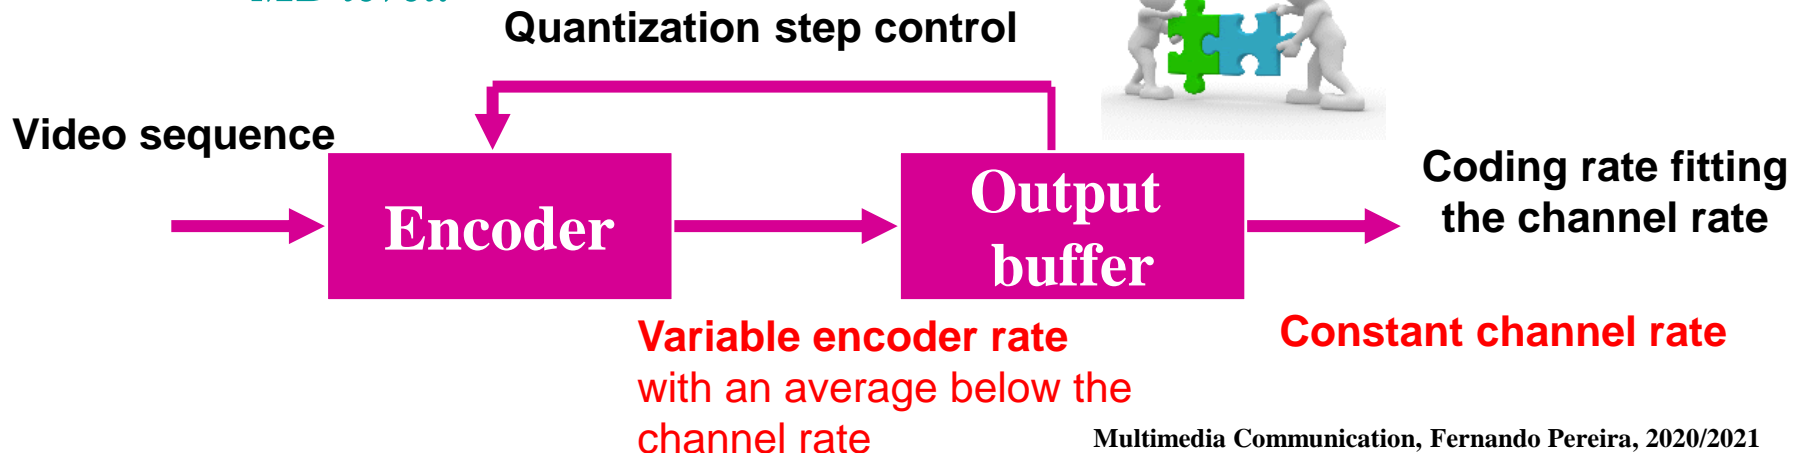

# Quantization Step versus Buffer Fullness

The bitrate control solution recognized as most efficient controls the MB quantization step, e.g. as a function of the output buffer fullness.

The granularity of this control is associated to the 31 quantization step values available; the frequency of change may be at MB level.

Quantization step

# Matching the Encoder Variable Rate with the Channel Constant Rate

**Variable content**  
**Variable rate**  
**Need to adapt**

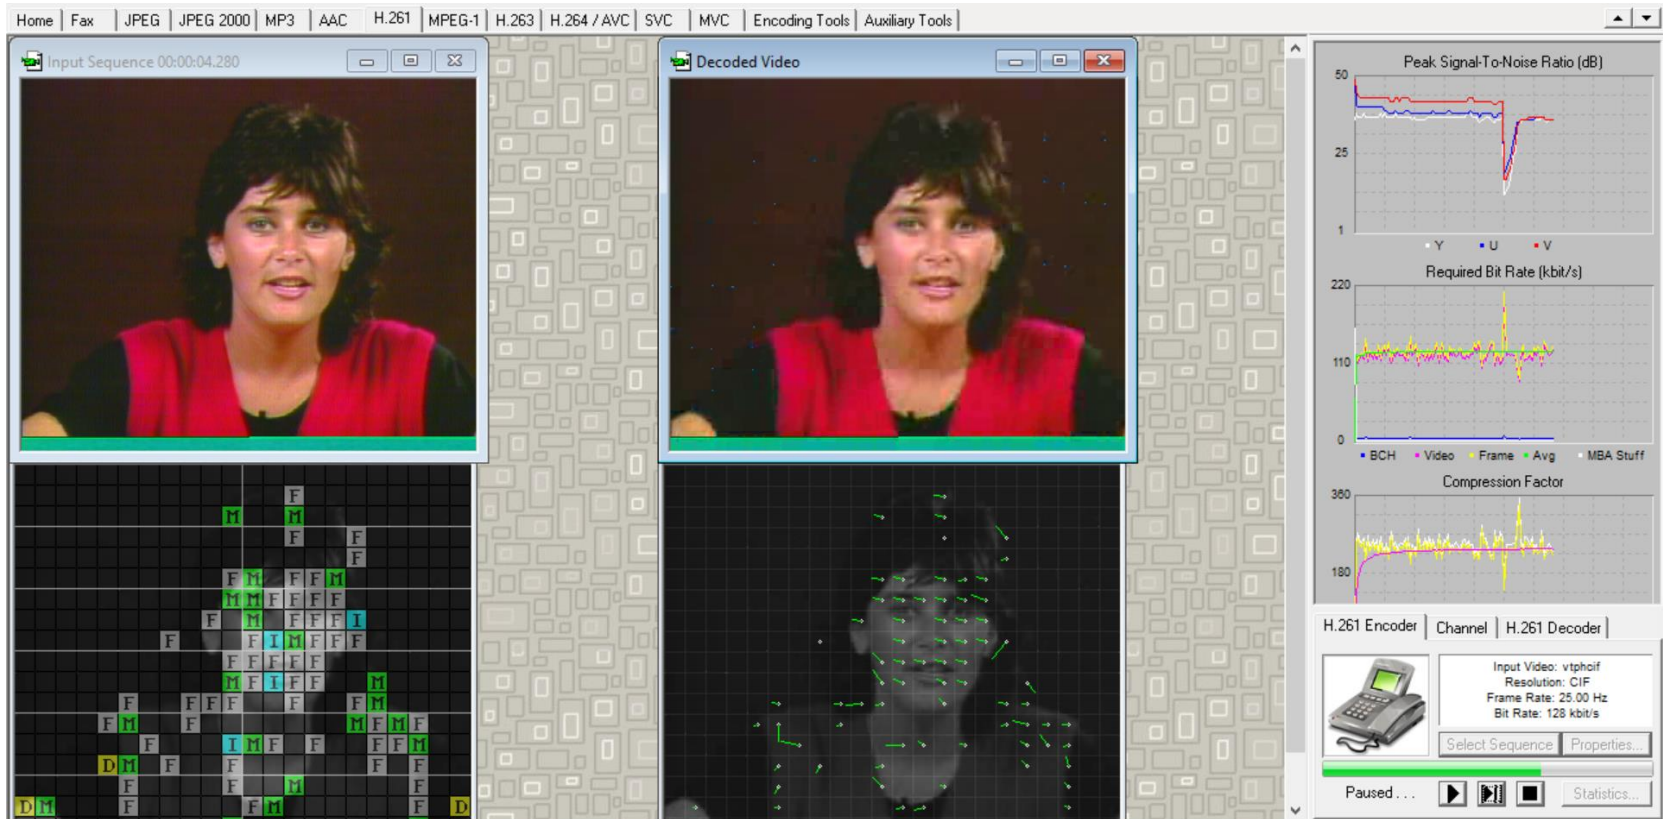

**Constant rate channel**  
**Uniform resources**

**The final video quality depends on:**

- **The (constant) channel rate**
- **The (spatially and temporally varying) content**
- **The quantization selection algorithm**
- **The (limited) buffer size (for the critical moments)**

# Let's Play and See ...

*I – Intra coding;*

*D – Inter coding without motion compensation (only error differences);*

*M – Inter coding with motion compensation;*

*F – Inter coding with motion compensation and the in-loop filter;*

*O - Overflow (indicating that the output buffer is too full and no bits may be sent).*
